Theorem

One can write down a (multivariate) polynomial p, with integer coefficients, that has a solution in natural numbers if and only if ZFC^{*a*} is inconsistent.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

^aZermelo-Fraenkel Set Theory with the Axiom of Choice

Theorem

One can write down a (multivariate) polynomial p, with integer coefficients, that has a solution in natural numbers if and only if ZFC^{*a*} is inconsistent.

 $^{a}\mathbf{Z}\text{ermelo-}\mathbf{F}\text{raenkel}$ Set Theory with the Axiom of Choice

 In fact, one can take p to have at most 9 variables, or to be a quartic (but not both at once). Moreover, the theorem doesn't use any special properties of ZFC!

Theorem

One can write down a (multivariate) polynomial p, with integer coefficients, that has a solution in natural numbers if and only if ZFC^{*a*} is inconsistent.

 $^{a}\mathbf{Z}\text{ermelo-}\mathbf{F}\text{raenkel}$ Set Theory with the Axiom of $\mathbf{C}\text{hoice}$

- In fact, one can take p to have at most 9 variables, or to be a quartic (but not both at once). Moreover, the theorem doesn't use any special properties of ZFC!
- Disclaimer: I'm not a logician. I'll skim over some technicalities and maybe make some nonstandard definitions.

I don't mean a polynomial like

$$p(x) = \begin{cases} x+1 & \text{if ZFC is consistent} \\ x-1 & \text{if ZFC is inconsistent} \end{cases}$$

This is cheating!

- Nor do I mean a polynomial like $p(x) = x^2 + 1$, since ZFC proves that this has no (natural) solutions. If this is our p, then ZFC is consistent, and also proves its own consistency, which contradicts Gödel's second incompleteness theorem.
- So *p* must be fairly complicated if ZFC is consistent, then *p* has no solutions, but ZFC doesn't prove this!

Some terminology

Let $S \subseteq \mathbb{N}$.

- Say that S is recursively enumerable (r.e. for short) if there is an algorithm A, that takes natural numbers as input, that halts on input n if and only if n ∈ S.
- Equivalently, there's an algorithm *B*, that takes infinite time to run, that prints out precisely the elements of *S*. Intuitively, given *A*, run *A*[*n*] at time *n*, and whenever *A*[*n*] finishes print *n*. Given *B* and *n*, just run *B* and check whether *n* shows up.
- For example the set of prime numbers is r.e.
- Note that non-r.e. sets must exist by a cardinality argument!

Say that S is diophantine¹ if there is a polynomial q(x₀,..., x_m) with coefficients in Z such that n ∈ S if and only if there exist a₁,..., a_m ∈ N with q(n, a₁,..., a_m) = 0.

¹Named after **Diophantus**, 3^{rd} century Greek mathematician who studied these kinds of equations.

- Say that S is diophantine¹ if there is a polynomial q(x₀,..., x_m) with coefficients in Z such that n ∈ S if and only if there exist a₁,..., a_m ∈ N with q(n, a₁,..., a_m) = 0.
- Clearly a diophantine set is r.e. just enumerate all tuples of natural numbers (n, a₁,..., a_m), plug them into q, and if the answer is zero then add n to the list. Is the converse true?

¹Named after **Diophantus**, 3rd century Greek mathematician who studied these kinds of equations. $(\Box \rightarrow \langle \Box \rangle \land \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \langle \Xi \rightarrow \rangle \land \Box \rightarrow \langle \Xi \rightarrow \rangle$

- Say that S is diophantine¹ if there is a polynomial q(x₀,..., x_m) with coefficients in Z such that n ∈ S if and only if there exist a₁,..., a_m ∈ N with q(n, a₁,..., a_m) = 0.
- Clearly a diophantine set is r.e. just enumerate all tuples of natural numbers (n, a₁,..., a_m), plug them into q, and if the answer is zero then add n to the list. Is the converse true?

Theorem (Matiyasevich–Robinson–Davis–Putnam, 1970)

Any recursively enumerable set S is diophantine. Moreover, given an algorithm that prints out S, we can write down a polynomial q.

¹Named after **Diophantus**, 3^{rd} century Greek mathematician who studied these kinds of equations.

 Question: Is there an algorithm A, that accepts polynomials over Z as arguments, that will tell us whether p has a root in N or not?

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- Question: Is there an algorithm A, that accepts polynomials over Z as arguments, that will tell us whether p has a root in N or not?
- MRDP tells us that if the answer is yes, then every r.e. set S is recursive, meaning that there's an algorithm that accepts natural numbers n as input and tells us whether or not n ∈ S. To see this, given S, we can write down p, and then apply A to q := p(n, x₂,..., x_m), since n ∈ S if and only if q has roots.

- Question: Is there an algorithm A, that accepts polynomials over Z as arguments, that will tell us whether p has a root in N or not?
- MRDP tells us that if the answer is yes, then every r.e. set S is recursive, meaning that there's an algorithm that accepts natural numbers n as input and tells us whether or not n ∈ S. To see this, given S, we can write down p, and then apply A to q := p(n, x₂,..., x_m), since n ∈ S if and only if q has roots.
- Since there exist r.e. sets which are not recursive, no such A can exist.

- If S is a r.e. set (with $0 \notin S$), by the MRDP theorem it's diophantine. Take a polynomial $M(x_0, \ldots, x_m)$ such that $n \in S$ if and only if $M(n, x_1, \ldots, x_m)$ has a solution in natural numbers. Replacing M by M^2 if necessary, we may assume that M is nonnegative. Then setting $Q := x_0(1 M)$, we see that the positive values taken by Q as x_0, \ldots, x_m range across \mathbb{N} are precisely the members of S.
- Jones, Sato, Wada and Wiens wrote down such a polynomial *Q* when *S* is the set of prime numbers:

$$(k+2)\{1 - [wz + h + j - q]^2 - [(gk + 2g + k + 1) \cdot (h + j) + h - z]^2 - [2n + p + q + z - e]^2 - [16(k + 1)^3 \cdot (k + 2) \cdot (n + 1)^2 + 1 - f^2]^2 - [e^3 \cdot (e + 2)(a + 1)^2 + 1 - o^2]^2 - [(a^2 - 1)y^2 + 1 - x^2]^2 - [16r^2y^4(a^2 - 1) + 1 - u^2]^2 - [((a + u^2(u^2 - a))^2 - 1) \cdot (n + 4dy)^2 + 1 - (x + cu)^2]^2 - [n + i + v - y]^2 - [(a^2 - 1)l^2 + 1 - m^2]^2 - [ai + k + 1 - i - i]^2 - [p + i(a - n - 1) + b(2an + 2a - n^2 - 2n - 2) - m]^2 - [q + y(a - p - 1) + s(2ap + 2a - p^2 - 2p - 2) - x]^2 - [z + pi(a - p) + i(2ap - p^2 - 1) - pm]^2$$

Figure: A polynomial whose positive values (as a, \ldots, z range across \mathbb{N}) are precisely the prime numbers. It also takes negative values; e.g. -76.

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- Code up proofs in ZFC as natural numbers (Gödel numbering)
- Write an algorithm that looks at a natural number and decides whether it codes a proof of a contradiction in ZFC
- Get a r.e. set S expressing consistency of ZFC
- Apply the MRDP theorem to S to get the polynomial p.

- A theory T is a pair (σ, A) where σ, the signature, is a tuple (F, R, C) of function symbols, relation symbols, and constant symbols, and A is a set of axioms.
- Example: the theory of abelian groups has signature (+,0) and axioms including ∀x∀y∀z((x + y) + z = x + (y + z)) and ∀x∃y(x + y = 0).
- A model of a theory T is a set M with functions M → M, relations on M, and constants in M, all satisfying the axioms.
- (ℤ/5ℤ, +) is a model of the theory of abelian groups. (ℝ, +) is a model. S₃ is not a model. (ℕ, +) is not a model.

Model theory, 2

- A proof of a sentence φ from a set of sentences Σ is a list of sentences φ₁,..., φ_n with φ_n = φ and where φ_{i+1} follows from φ_i by some deduction rules applied to the previous sentences and Σ.
- A theorem of T is a sentence φ with a proof. Write T ⊢ φ to mean that T proves φ. T proves φ if and only if φ is true in all models (Gödel's completeness theorem).
- For the theory of abelian groups, 0 + 0 = 0 is a theorem.
 ∀x(x + x + x = 0) is not a theorem, since not every abelian group is 3-torsion. But its negation ∃x(x + x + x ≠ 0) is not a theorem either, since it's false in Z/3Z. We might say that ∀x(x + x + x = 0) is independent.

Model theory, 3

- A theory *T* is **effectively axiomatisable** if there's an algorithm that runs in infinite time that prints out precisely all of the theorems of *T*.
- Some examples of effectively axiomatised theories:
 - 'Algebraic' theories: groups, rings, Lie algebras,...
 - 'Arithmetic' theories: Peano arithmetic, Robinson arithmetic (PA without induction), Presburger arithmetic (PA without multiplication),...
 - Set theories: ZFC, NBG (ZFC with proper classes),...
 - Order theories: Partial orders, total orders, well-orders, real closed fields,...
 - Any theory with a finite list of axioms and a finite signature.

 Non-examples: any complete undecidable theory, e.g. True Arithmetic - all statements true in N.

Gödel numbering

- Suppose T is effectively axiomatisable. Then T has countably many symbols (logical symbols, plus symbols from σ, plus variables) so we can associate to each symbol a positive natural number. If φ is a sentence then we can associate a number [φ] by taking prime powers.
- For example if we say $\lceil 0 \rceil = 1$, $\lceil + \rceil = 2$ and $\lceil = \rceil = 3$ then we get $\lceil 0 + 0 = 0 \rceil = 2^1 \cdot 3^2 \cdot 5^1 \cdot 7^3 \cdot 11^1 = 339,570$. The number $\lceil \phi \rceil$ is called the **Gödel number** of ϕ .
- We can code up proofs in *T* similarly. Whether or not a number codes a proof can be checked algorithmically.
- If *T* can also talk about arithmetic (e.g. if *T* is ZFC or PA), then we can do this encoding *inside T*, and so *T* can talk about itself.

Gödel's First Incompleteness Theorem

If T is any consistent effectively axiomatisable theory which contains enough arithmetic, then there is a sentence G_T , the **Gödel sentence**, which is neither provable nor disprovable in T.

Proof idea:

- Define a predicate NP(n) to mean 'T does not prove the sentence with Gödel number n'.
- use a clever diagonalisation argument to show that for any predicate Q, there is a sentence φ such that
 T ⊢ (φ ↔ Q(⌈φ⌉).
- Apply the above to the predicate NP to obtain a sentence G_T such that T ⊢ (G_T ↔ NP([G_T]))

So informally, G_T is true if and only if T does not prove G_T . It follows that G_T is neither provable nor disprovable, and in reasonable circumstances² must be true.

Gödel's Second Incompleteness Theorem

If T is any consistent effectively axiomatisable theory which contains enough arithmetic, then T does not prove its own consistency.

Proof idea:

- Define the sentence Con(T) to mean NP([0 = 1]).
- Code up the proof of the first incompleteness theorem inside T to see that $T \vdash (\operatorname{Con}(T) \rightarrow G_T)$.
- So if $T \vdash \operatorname{Con}(T)$ then $T \vdash G_T$, which is a contradiction. So T can't prove $\operatorname{Con}(T)$.

²For example, in models of T + Con(T).

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三 少々ぐ

• Consider your favourite contradiction \perp of T. This might be $\forall x (x \neq x)$, or if T contains enough arithmetic it might be 0=1.

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

- Consider your favourite contradiction \perp of T. This might be $\forall x (x \neq x)$, or if T contains enough arithmetic it might be 0=1.
- Since T is effectively axiomatisable, given a natural number n we can algorithmically check whether n encodes a proof of ⊥.

- Consider your favourite contradiction \perp of T. This might be $\forall x (x \neq x)$, or if T contains enough arithmetic it might be 0=1.
- Since T is effectively axiomatisable, given a natural number n we can algorithmically check whether n encodes a proof of ⊥.
- This gives us a r.e. set S such that n ∈ S if and only if n codes for a proof of ⊥ in T. The MRDP theorem tells us that S must be diophantine.

- Consider your favourite contradiction \perp of T. This might be $\forall x (x \neq x)$, or if T contains enough arithmetic it might be 0=1.
- Since T is effectively axiomatisable, given a natural number n we can algorithmically check whether n encodes a proof of ⊥.
- This gives us a r.e. set S such that n ∈ S if and only if n codes for a proof of ⊥ in T. The MRDP theorem tells us that S must be diophantine.
- So any effectively axiomatisable theory T has an associated polynomial p_T that has solutions in \mathbb{N} if and only if T is inconsistent. One can write down such a p_T algorithmically from the axioms of T. There are lots of different polynomials, since e.g. they depend on our choice of Gödel numbering.

- Let's suppose that T is consistent and contains enough arithmetic (so it satisfies the hypotheses of the Incompleteness Theorems). In particular p_T has no roots.
- We can code up the previous proof inside *T* to see that *T* ⊢ ('*p*_T has no roots' ↔ Con(*T*)). Hence *T* ⊭ '*p*_T has no roots', otherwise *T* would prove Con(*T*).
- But if T doesn't prove a sentence φ, there must be models where φ is false. In particular there are models of T (necessarily models of T + ¬Con(T)) where p_T has a root!
- In such a model, any root of p_T must necessarily be a nonstandard natural number, corresponding to a proof of ⊥ of nonstandard length.
